Sampling Distributions and Data Descriptions

CHAPTER 8

Theorem 8.3:

If independent samples of size n_1 and n_2 are drawn at random from two populations, discrete or continuous, with means μ_1 and μ_2 and variances σ_1^2 and σ_2^2 , respectively, then the sampling distribution of the differences of means, $\bar{X}_1 - \bar{X}_2$, is approximately normally distributed with mean and variance given by

$$\mu_{\bar{X}_1-\bar{X}_2} = \mu_1 - \mu_2 \text{ and } \sigma_{\bar{X}_1-\bar{X}_2}^2 = \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}$$

Hence,

$$Z = \frac{(\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2)}{\sqrt{(\sigma_1^2/n_1) + (\sigma_2^2/n_2)}}$$

is approximately a standard normal variable.

Ex 1:

The mean height of 15-year-old boys is 175 cm and the variance is 64. For girls, the mean is 165 and the variance is 36. If 25 boys and 25 girls were sampled,

what is the probability that the mean height of the sample of boys would be at least 6 cm higher than the mean height of the sample of girls?

Solution :

In this case, $\mu 1 = 175$, $\sigma 1 = 8$, n1 = 25,

 $\mu 2 = 165$, $\sigma 2 = 6$, n2 = 25,

We need to calculate the probability $P(X1 - X2 \ge 6)$.

 $\sigma_{\bar{X}_A - \bar{X}_B}^2 = \frac{\sigma_A^2}{n_A} + \frac{\sigma_B^2}{n_B} =$ 64/25 + 36/25 = 100/25 = 4
Sqrt (4) = 2 $P(X1 - X2 \ge 6) = P(Z \ge (6 - (175 - 165))/2) = P(Z \ge -4/2) = P(Z \ge -2)$ $= 1 - P(Z \le 2) = 1 - 0.0228 = 0.9772$

Theorem 8.4:

If S^2 is the variance of a random sample of size *n* taken from a normal population having the variance σ^2 , then the statistic

$$\chi^2 = \frac{(n-1)S^2}{\sigma^2} = \sum_{i=1}^n \frac{(X_i - \bar{X})^2}{\sigma^2}$$

has a chi-squared distribution with v = n - 1 degrees of freedom.

Ex 2:

It is believed that first-year salaries for newly qualified accountants follow a normal distribution with a variance of \$2500. A random sample of 16 observations was taken. Find the probability that the sample variance is less than \$1500.

Solution :

In this case, $\sigma^2 = 2500$, n = 16,

We need to calculate the probability $P(S^2 < 1500)$.

$$\chi^2 = \frac{(n-1)S^2}{\sigma^2} =$$

$$(16-1)1500/2500 = 15*1500/2500 = 9$$

$$P(S^{2}<1500) = P(\chi^{2} < 9) = ??$$

$$\chi^{2}{}_{\alpha} = 9 \text{ and with 15 degree of freedom has } \alpha = 0.85 = P(\chi^{2} >= 9)$$

$$P(S^{2}<1500) = P(\chi^{2} < 9) = 1 - P(\chi^{2} >= 9) = 1 - 0.85 = 0.15$$

t-Distribution

8.6 t-Distribution

Use of the Central Limit Theorem and the normal distribution is certainly helpful in this context.

However, it was assumed that the population standard deviation is known.

This assumption may not be unreasonable in situations where the engineer is quite familiar with the system or process.

in many experimental scenarios, knowledge of σ is certainly no more reasonable than knowledge of the population mean μ . Often, in fact, an estimate of σ must be supplied by the same sample information that produced the sample average \bar{x} .

8.6 t-Distribution

in many experimental scenarios, knowledge of σ is certainly no more reasonable than knowledge of the population mean μ . Often, in fact, an estimate of σ must be supplied by the same sample information that produced the sample average \bar{x} .

As a result, a natural statistic to consider to deal with inferences on μ is

$$T = \frac{\bar{X} - \mu}{S/\sqrt{n}},$$

since S is the sample analog to σ .

8.6 t-Distribution

In developing the sampling distribution of T,

we shall assume that our random sample was selected from a normal population. We can then write

Multiply by σ/σ

$$T = \frac{(\bar{X} - \mu)/(\sigma/\sqrt{n})}{\sqrt{S^2/\sigma^2}} = \frac{Z}{\sqrt{V/(n-1)}},$$

where

$$Z = \frac{\bar{X} - \mu}{\sigma / \sqrt{n}}$$

has the standard normal distribution and

$$V = \frac{(n-1)S^2}{\sigma^2}$$

has a chi-squared distribution with v = n - 1 degrees of freedom.

Corollary 8.1:

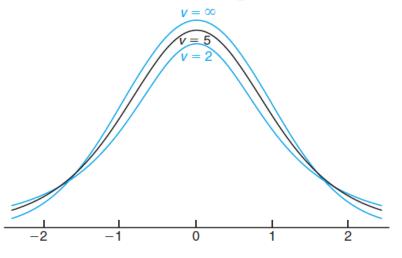

Let X_1, X_2, \ldots, X_n be independent random variables that are all normal with mean μ and standard deviation σ . Let

$$\bar{X} = \frac{1}{n} \sum_{i=1}^{n} X_i$$
 and $S^2 = \frac{1}{n-1} \sum_{i=1}^{n} (X_i - \bar{X})^2.$

Then the random variable $T = \frac{\bar{X} - \mu}{S/\sqrt{n}}$ has a *t*-distribution with v = n - 1 degrees of freedom.

What Does the *t*-Distribution Look Like?

The distribution of T is similar to the distribution of Z in that they both are symmetric about a mean of zero. Both distributions are bell shaped, but the tdistribution is more variable, owing to the fact that the T-values depend on the fluctuations of two quantities, \bar{X} and S^2 , whereas the Z-values depend only on the changes in \bar{X} from sample to sample. The distribution of T differs from that of Zin that the variance of T depends on the sample size n and is always greater than 1. Only when the sample size $n \to \infty$ will the two distributions become the same.

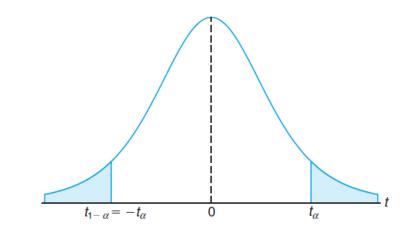

Figure 8.8: The *t*-distribution curves for v = 2, 5, and ∞ .

Figure 8.9: Symmetry property (about 0) of the t-distribution.

Table A.4 (continued) Critical Values of the t-Distribution

Example 8.8:

The *t*-value with v = 14 degrees of freedom that leaves an area of 0.025 to the left, and therefore an area of 0.975 to the right, is

Example 8.8:

The *t*-value with v = 14 degrees of freedom that leaves an area of 0.025 to the left, and therefore an area of 0.975 to the right, is

$$t_{0.975} = -t_{0.025} = -2.145.$$

Example 8.9:

Find $P(-t_{0.025} < T < t_{0.05})$.

Since $t_{0.05}$ leaves an area of 0.05 to the right, and $-t_{0.025}$ leaves an area of 0.025 to the left, we find a total area of

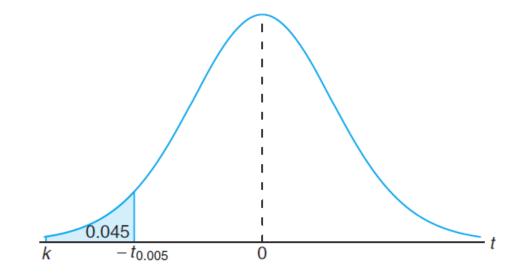

1 - 0.05 - 0.025 = 0.925

between $-t_{0.025}$ and $t_{0.05}$. Hence

 $P(-t_{0.025} < T < t_{0.05}) = 0.925.$

Example 8.10:

Find k such that P(k < T < -1.761) = 0.045 for a random sample of size 15 selected from a normal distribution and $\frac{\overline{X} - \mu}{s/\sqrt{n}}$.

Find k such that P(k < T < -1.761) = 0.045 for a random sample of size 15 selected from a normal distribution and $\frac{\overline{X} - \mu}{s/\sqrt{n}}$.

From Table A.4 we note that 1.761 corresponds to $t_{0.05}$ when v = 14. Therefore, $-t_{0.05} = -1.761$. Since k in the original probability statement is to the left of $-t_{0.05} = -1.761$, let $k = -t_{\alpha}$. Then, from Figure 8.10, we have

 $0.045 = 0.05 - \alpha$, or $\alpha = 0.005$.

Hence, from Table A.4 with v = 14,

 $k = -t_{0.005} = -2.977$ and P(-2.977 < T < -1.761) = 0.045.

Example 8.11:

A chemical engineer claims that the population mean yield of a certain batch process is 500 grams per milliliter of raw material. To check this claim he samples 25 batches each month. If the computed *t*-value falls between $-t_{0.05}$ and $t_{0.05}$, he is satisfied with this claim. What conclusion should he draw from a sample that has a mean $\bar{x} = 518$ grams per milliliter and a sample standard deviation s = 40 grams? Assume the distribution of yields to be approximately normal.

Solution :

From Table A.4 we find that $t_{0.05} = 1.711$ for 24 degrees of freedom. Therefore, the engineer can be satisfied with his claim if a sample of 25 batches yields a *t*-value between -1.711 and 1.711. If $\mu = 500$, then

$$t = \frac{518 - 500}{40/\sqrt{25}} = 2.25,$$

a value well above 1.711. The probability of obtaining a *t*-value, with v = 24, equal to or greater than 2.25 is approximately 0.02. If $\mu > 500$, the value of *t* computed from the sample is more reasonable. Hence, the engineer is likely to conclude that the process produces a better product than he thought.

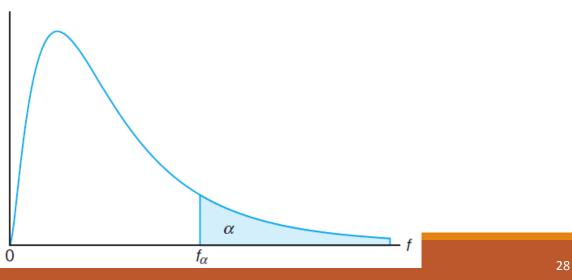

F-Distribution

F-Distribution

The statistic F is defined to be the ratio of two independent chi-squared random variables, each divided by its number of degrees of freedom. Hence, we can write

$$F = \frac{U/v_1}{V/v_2},$$

where U and V are independent random variables having chi-squared distributions with v_1 and v_2 degrees of freedom, respectively. We shall now state the sampling distribution of F.

Theorem 8.8:

If S_1^2 and S_2^2 are the variances of independent random samples of size n_1 and n_2 taken from normal populations with variances σ_1^2 and σ_2^2 , respectively, then

$$F = \frac{S_1^2 / \sigma_1^2}{S_2^2 / \sigma_2^2} = \frac{\sigma_2^2 S_1^2}{\sigma_1^2 S_2^2}$$

has an *F*-distribution with $v_1 = n_1 - 1$ and $v_2 = n_2 - 1$ degrees of freedom.

Table A.6 (continued) Critical Values of the F-Distribution

Writing $f_{\alpha}(v_1, v_2)$ for f_{α} with v_1 and v_2 degrees of freedom, we obtain

$$f_{1-\alpha}(v_1, v_2) = \frac{1}{f_{\alpha}(v_2, v_1)}.$$

Thus, the $f\mbox{-value}$ with 6 and 10 degrees of freedom, leaving an area of 0.95 to the right, is

$$f_{0.95}(6,10) = \frac{1}{f_{0.05}(10,6)} = \frac{1}{4.06} = 0.246.$$
